# **I. Introduction**

## **I.1 Sample evaluation**

In the first section of the report, we provide an overview of the extent to which the sampling requirements were met and discuss discrepancies between the achieved and target sample profiles (according to the available sample frame information).

## **I.2 Weighting**

In the second section of the report, we provide full details of the weights that have been applied to the data – both within and across countries. This includes documenting the distributions of the weighting variables for each country, and the number of cases in each country for which the (design) weight was trimmed. We will also document the impact of the weighting scheme on the effective sample size. At the end of this section, tables are provided showing the weighted and unweighted distribution of the sample, and the distribution of the population on key variables.

Note that initially, the post-stratification weighting for the EWCS was based on the labour force survey (LFS) for 2014. The LFS 2015 reference statistics were not yet available during the fieldwork and during the drafting of the methodological reports. Because the fieldwork was conducted in 2015, LFS reference statistics for 2015 reflect better the desired distribution of the respondents. Therefore, Eurofound re-calibrated the post-stratification weights to 2015, using the exact same method described in the sampling evaluation and weighting report. The overview report and other upcoming research reports as well as the survey mapping tool are based on the 2015 post-stratification weighting. The relevant information provided in the methodological reports, including this one, is based on the 2014 weighting.

## II. Sample evaluation

### II.1 Planned and achieved sample size

Eurofound required a reference sample size of 1,000 per country – except in the following countries, where the reference sample size was larger: Poland (1,200); Spain (1,300); Italy (1,400); France (1,500); the UK (1,600), Germany and Turkey (both 2,000). Eurofound also offered countries the opportunity to top-up their sample; this was taken up by Belgium (2,500), Slovenia (1,600) and Spain (3,300). Across all countries, the net sample size (i.e. achieved sample size) was somewhat larger than the planned sample size.<sup>1</sup>

## II.2 Planned and achieved sample breakdowns

The sample in each country was stratified. Each country was divided into strata defined by region and degree of urbanization. Eurofound specified that regions had to be at the level of NUTS 2 or equivalent in each country. Eurostat's degree of urbanisation indicator DEGURBA<sup>2</sup> was also used in as many countries as possible. This indicator has three categories: densely populated area, intermediate density area, and thinly populated area. The sample was allocated to the strata proportionately to the number of people in employment in each stratum. The population statistics were derived from Eurostat's Labour Force Survey (LFS) or an equivalent source. More details about the sources used for stratification in each country can be found in the Sampling Implementation Report.

At the start of the fieldwork period, a requirement was set for the number of addresses issued not to exceed three times the number of target interviews; in other words, interviewers were required to work only with up to three times the number of open addresses for which they required interviews ("3:1" rule). Once a country reached 75% of their target sample size, a distribution showing their achieved sample was created and compared to the planned sample breakdown. The percentage difference between the two figures (per cell and overall) was identified and highlighted. All countries were advised to concentrate their efforts in the cells which were furthest from the planned sample profile in the last few weeks of fieldwork.

In some countries, slow fieldwork progress necessitated an amendment of the requirement for the number of addresses issued to interviewers not to exceed three times the remaining number of target interviews. The relaxation entailed sample yield rates being calculated for each country, and estimating the number of additional cases required. National partners were allowed to issue additional top-up sample only in the poorest-performing PSUs. The following countries were assisted by the relaxation of the 3:1 rule: Austria, Belgium, Croatia, the Netherlands, Spain and Switzerland.

### Comparison of planned and achieved (final) sample breakdowns

The planned sample breakdown and achieved (final) sample distributions per country are displayed in the tables in Annex. Tables 2a, 2b and 2c compare the planned sample breakdowns and achieved (final) sample distributions per country, and provide information about the minimum, maximum and mean gross sample per PSU and the minimum, maximum and mean achieved number of interviews per PSU. Table 2a presents this info by sampling stratum (region x degree of urbanisation), Table 2b focuses on sampling regions, and Table 2c on degree of urbanisation.

The penultimate column in the tables shows the absolute difference (in percentage points) in the size of each cell between the planned and achieved distribution; deviations larger than 1 percentage point are marked in red. The relative differences in cell size are presented in the last column; in this column, deviations of more than 10% are marked in red.

In 15 countries, the deviations in the size of each cell between the distribution across stratification categories of the net sample and the distribution of the universe do not exceed 1 percentage point. This means that in 43% of countries the distributions across stratification categories of the gross sample closely approximates the distributions of the universe (sampling plan).<sup>3</sup>

---

<sup>2</sup> [http://ec.europa.eu/eurostat/ramon/miscellaneous/index.cfm?TargetUrl=DSP\\_DEGURBA](http://ec.europa.eu/eurostat/ramon/miscellaneous/index.cfm?TargetUrl=DSP_DEGURBA)

<sup>3</sup> QA# 22: Percentage of countries where the distributions across stratification categories of the net sample closely approximates the distributions of the universe (sampling plan) (deviations in the proportional size of each of the strata between the two should not exceed 1 percentage point) [Target: 100%]: 15 countries (or 43%).

In 18 countries, at least one deviation of between 1 and 3 percentage points was observed. In five of these countries (Austria, the Czech Republic, Finland, the Netherlands, Norway and Switzerland), these deviations were positive, i.e. the target size of the sampling cell was exceeded. In three countries (Germany and Sweden), the deviations were negative, i.e. the target size of the sampling cell was not reached. In the remaining countries, both positive and negative deviations of between 1 and 3 percentage points were observed; this was the case in Belgium, Greece, Latvia, Luxembourg, Malta, Romania, Slovakia, Slovenia, Turkey and the UK.

In the remaining two countries (Ireland and Estonia), a comparison of the distribution across stratification categories of the net sample and the distribution of the universe showed larger deviations (between 1.3 and 10.1 percentage points).

In all countries (the exceptions being Estonia and Ireland – see below), the deviations in cell size between the distribution across stratification categories of the net sample and the distribution of the universe can be explained by differences in eligibility rates and response rates across geographic regions and urbanisation levels. For example, Table 2c shows that, in two-thirds of the countries, in urbanised PSUs, on average, more addresses were needed to reach the target number of interviews than in non-urbanised PSUs. For example, in France, in rural settlements, an average of 43.1 addresses was needed to complete, on average, 10.6 interviews; the number of addresses increased to 61.9 in urban areas with 100,000 or more inhabitants (excl. Paris) and 71.6 in Paris. In Italy and Luxembourg, an opposite trend was observed (i.e. more addresses were contacted in rural areas). In seven countries (Cyprus, the Czech Republic, Germany, Portugal, Romania, Slovakia and Switzerland), no difference was observed in the “success rate” across PSUs in terms of urbanisation level.

**Ireland:** In Ireland, a difference in success rate (i.e. number of addresses needed to complete the target number of interviews) was observed across regions and urbanisation levels. For example, in Dublin, on average, 29.9 addresses were contacted per PSU, to complete on average 7 interviews (a ratio of 4.3); in the thinly populated parts of Connacht/Ulster, however, 32.0 addresses generated, on average, 18.9 interviews (a ratio of 1.7). Ireland adhered to the 3:1 rule for sample implementation throughout the whole fieldwork period; the team did not issue additional addresses in strata that were furthest from target (the poorest-performing PSUs, e.g. in Dublin), but issued additional addresses across all PSUs.

**Estonia:** The fieldwork team in Estonia had difficulties getting access to apartments in richer areas of Tallinn<sup>4</sup>; moreover, some PSUs in Tallinn were described as having rich parts with higher refusals. In the final sample breakdown, the size of sampling cell “Tallinn” was 5.5 percentage points below the target size according to the distribution of the universe. Deviations were also observed in the following counties: Hiiu county, Järva county, Põlva county and Rapla county. In each of these counties, the planned sample distribution deviated from the actual PSU selection, and the rural/urban categorisation was not respected.

### **Comparison of planned and achieved sample breakdowns – interim and final data for Finland, Spain and Sweden**

In Finland, Spain and Sweden, fieldwork was not yet completed by the end of July – when a preliminary data set had to be delivered to Eurofound. In Finland and Sweden, at the time of the delivery of the preliminary data set, all sample units in the original gross sample had been contacted and no additional contact attempts were required; however, the final target number of interviews had not yet been reached. As such, in both countries, additional units were sampled in PSUs where the target number of interviews had not yet been reached, and interviewers conducted interviews in these PSUs during the summer months.

In Spain, a different approach was used. For the preliminary data delivery, the Spanish agency focused on completing fieldwork in a smaller, but representative sample of PSUs (289 PSUs from the original sample of 759 PSUs, distributed across 72 of the 78 sampling strata). During the summer months, fieldwork continued in the remaining PSUs (distributed across all but one of the 78 sampling strata).

---

<sup>4</sup> Reflected in a final outcome for 31 cases of ‘Unsuccessful attempt to get inside the building, contact the household’.

Having fieldwork continuing during the summer months was not recommended as it was harder to find available interviewers and respondents; this could potentially have an impact on the response rate. Table 2d (in Annex) presents, for each sampling stratum, the minimum, maximum and mean gross sample per PSU and the minimum, maximum and mean achieved number of interviews per PSU – distinguishing between the original sample and the additional sample completed during the summer months. Although in some sampling strata, more sample units were needed to complete the target number of interviews during the summer months; in a majority of sampling strata, the opposite was observed.

### III. Weighting

#### III.1 Steps used for weighting

There are a series of steps in weighting:

**Step 1:** adjusting samples with design weights in a way that properly reflects probabilities of selection;

**Step 2:** adjusting for differences between the sample and population distributions on variables that are considered to be related to key outcomes (via post-stratification weighting);

**Step 3:** given the cross-national focus of the ECWS, the last step of the weighting adjustment consists of developing cross-national or population-size weights for each country covered.

#### *Design weights*

In the EWCS, most individual country samples were drawn in three stages: (1) the selection of PSUs, (2) the selection of addresses/households within these PSUs, and (3) the selection of one person within each household (the last step is not necessary for register-based samples). The selection probabilities were recorded at each stage. These records were subsequently used to calculate *design weights* (also called *sampling weights* or *base weights*) which are the inverse of the product of the inclusion probabilities at each stage.

##### **(1) PSU selection weight ( $w_i$ )**

PSUs were randomly selected from each stratum (of the sample breakdown); the required number of PSUs was selected using PPS (probability proportional to size).

The PSU selection weight  $w_i$  is calculated as the inverse of the PSU selection probability,  $p_i$ :

$$w_i = 1 / p_i$$

where:

$$p_i = w_{1b} * w_{1a_i} / \sum w_{1a_i}$$

$w_{1b}$  = number of PSUs sampled

$w_{1a_i}$  = size of PSU  $i$

##### **(2) Conditional PSU responding weight ( $w_u$ )**

Within each PSU, cases (addresses, individuals) were selected randomly from registers or from enumerated lists of addresses. All addresses were sorted before selections were made –by street name, then by the house number, then by flat number (if applicable) - to ensure a good spread of addresses across the PSU.

The conditional PSU responding weight is calculated as:

$$w_u = 1 / p_u$$

where:

$$p_u = w_{1d} / (u_i * w_{1c})$$

$w_{1d}$  = number of interviews completed in PSU $_i$

$u_i$  = total number of units on the frame for the PSU (note: across all countries,  $w_{1a_i}$  was used as proxy for  $u_i$ )

$w_{1c}$  = unit eligibility rate = (number of sampled units screened and found to eligible) / (number of sampled units successfully screened)

number of sampled units *successfully screened*:

- address-based samples: the interviewer was able to assess if there were any individuals in the sampled household who had worked for pay or profit during the preceding Monday to Sunday, aged 15 years and over<sup>5</sup>, and recorded this on the contact sheet (questions a10a and a10b);
- register-based samples: the interviewer was able to assess whether the sampled individual (aged 15 years and over) had worked for pay or profit during the preceding Monday to Sunday, and recorded this on the contact sheet (questions a10a and a10b).

number of sampled units *screened and found to eligible*

- address-based samples: the interviewer was able to assess that **at least one adult** in the sampled household had worked for pay or profit during the reference week;
- register-based samples: the interviewer was able to assess that the sampled individual had worked for pay or profit during the reference week.

PSU level eligibility estimates are based on small numbers of cases. If less than 20 individuals/households were successfully screened, the unit eligibility rate was estimated at stratum level. In some instances (52 PSUs), less than 20 individuals/households were screened at stratum level; in this case, the eligibility rate was estimated at region level. Finally, for one PSU (in Estonia), less than 20 individuals/households were screened at region level and the eligibility rate was estimated at urbanisation level.

In France, Ireland and Norway, the size measure for PSU selection was the size of the in-work population; as such, it was not necessary to estimate the unit eligibility rate.

---

<sup>5</sup> Aged 16 years or over in Bulgaria, Norway, Spain and the UK

### Individual selection weight (w<sub>le</sub>)

In countries using address-based samples, one eligible person belonging to the target population (employed, aged 15 years and over<sup>6</sup>) was randomly selected within every household, using a last birthday selection method. In these countries, this selection process is a third source of variation in selection probabilities. For example, persons in households with four persons aged 15 years and older in employment had a selection probability one-quarter that of a person on a single adult household.

w<sub>le</sub> = number of eligible (in work) adults in the sampled household

The individual selection weight is truncated at “4”. The main reason to truncate this value is that the composition of the sample is also affected by nonresponse; in a larger household, it is more likely that someone is at home when the interviewer visits – in other words, the selection probability for an individual in a larger household may in fact be more similar to that for an individual in a smaller one than it would appear at first sight.

### Calculation of pre-weight (w1\_freq)

The final pre-weight is calculated as:

$$w1\_freq = w_i * w_u * w1e$$

### Calculation of design weight (used as input for calculation of post-stratification weight) (w1\_scaled)

The pre-weight w1\_freq is then scaled to the sample size, i.e. the pre-weights are divided by their arithmetic mean. The distribution of rescaled pre-weights in each country were inspected and maximum values were truncated around the value of 4 in order to control sampling variance inflation.

When the weights of all sampled units are the same (i.e. all sample units have the same selection probability), the sample is referred to as *self-weighting*. Samples are rarely self-weighting; in the EWCS6, none of the countries achieved this goal of a *self-weighting* sample and several reasons can be mentioned to explain this:

- **No detailed information about “actual” PSU size:** although PSUs were selected with probability proportional to size, the size measure used in most countries was not that of the eligible population (employed individuals, aged 15 years and over<sup>7</sup>) but an approximation of this measure (e.g. number of addresses, number of adults).
- **Sample units not being selected at an appropriate rate within PSUs:** given that, in most countries, no information is available about the size of the target population in each PSU, the selection rate of sample units within PSUs is not perfectly linked to the PPS selection rate of PSUs (i.e. the higher selection probabilities of large PSUs are only partially corrected for by lower selection probabilities of sample units within these PSUs).
- **Different eligibility and response rates across PSUs:** Across all PSUs, a requirement was set to reach a final outcome code for all contacted addresses; in some countries, with large variation in eligibility and response rates across PSUs, this resulted in a large variation in the number of completed interviews per PSU. Most *self-weighting* designs, however, start from the assumption that an equal number of interviews is completed in each PSU.
- **Sampling of households/addresses instead of individual level samples:** in most countries, selection probabilities also varied due to the selection of one person for interview in each sampled household.

Norway and Denmark were the closest to a *self-weighting* sample; in Norway, the design weights varied between 0.79 and 1.21, and in Denmark, the weights varied between 0.78 and 1.24. Norway was one of the few countries for which the size measure for PSUs was the actual eligible population (the product of  $w_i * w_u$  only varied due to difference in the number of interviews per PSU); moreover, sampling was based on a register of individuals (i.e. no differential selection probabilities due to household size).

<sup>7</sup> Aged 16 years or over in Bulgaria, Norway, Spain and the UK

Denmark also used an individual-based sample, but the PSU size needed to be estimated. In Denmark, however, the variation in eligibility rates and response rates across PSUs was limited and this helps to explain the smaller variation in design weights.

Countries, such as Belgium, Ireland, Spain and the UK, were characterised by a large variation in design weights (and a relatively high number of weighting values that needed to be truncated); the main reason for this variation is the large variation in both eligibility rates and response rates across PSUs. For example, in Spain, the unit eligibility rate (w1c) varied between 4% and 57%, while the number of completed interviews per PSU varied between 0 and 12 interviews.<sup>8</sup>

**Figure 1: Distribution of the design weight (w1\_scaled), by country**

## Post-stratification weight

### Calculation of post-stratification weight ( $w_{ps}$ )

The initial design weights were corrected to adjust for non-response and improved by means of post-stratification. In order to ensure that the sample accurately reflects the socio-demographic structure of the target population, a post-stratification weighting procedure, using intercellular and marginal weighting, was carried out on a country-by-country basis.

This approach involved *rim* weighting (raking) using four weighting variables:

1. age by sex (four age bands<sup>9</sup> within each gender); source: LFS, 2014 (except AL: LFS, 2013) – Eurostat or local statistical office<sup>10</sup>
2. NUTS region:
  - a. NUTS1 region: DE, FR, IT, PL, UK, TK (source: Eurostat, LFS, 2014)
  - b. NUTS3 region (or other classification): CY, LV, EE, LT, LV, MT, IR, HR, SI, AL, MK, ME, RS, (source: national statistical office, LFS, 2011 to 2014)
  - c. NUTS2 region: remaining countries (source: Eurostat, LFS, 2014)
3. Industry (based on NACE Sector<sup>11</sup>); source: LFS, 2014 (except AL: LFS, 2013) – Eurostat or local statistical office
4. Occupation (8 categories based on ISCO 1-digit<sup>12</sup>); source: LFS, 2014 (except AL: LFS, 2013) – Eurostat or local statistical office

Post-stratification weights were calculated using pre-weighted data (i.e. data weighted by design weight) for each country. *Weight trimming*: A restriction was set for the post-stratification weight not to exceed a certain value (this value was set at 1.4 for the post-stratification step; combined with the pre-weights, this resulted in trimming the final post-stratification weights at a value of between 4 and 5).

### Calculation of the final individual country weights ( $w_4$ )

$$w_4 = w_{c1}/(\text{mean value of } w_{c1})$$

As a result of this scaling, unweighted and weighted sample sizes will be identical in each country.

Across all countries, a considerable proportion of cases have weights smaller than .3; in 24 countries, the proportion of stratification weights smaller than .3 exceeds 2%.

Across most countries, the proportion of post-stratification weights that were larger than 3 is below 2%; the exceptions are Ireland, Romania, Spain and Slovakia. In Table 6, it can be seen that Spain and Ireland are characterised by a relatively high rate of design weights that are larger than 3. In Romania and Slovakia, the proportion of design weights larger than 3 was smaller, but the weighting evaluation presented in Section III.3 shows that some deviations are observed between the universe statistics and unweighted samples.<sup>13</sup>

Figure 2: Distribution of the post-stratification weight (w4), by country

### *Cross-national weights*

Most countries in the EWCS have the same sample size, no matter the size of the in-work population in these countries. The mathematics of sampling prove that a sample of, for example, 1,000 respondents is equally useful in examining the opinions in a country with 10 million in-work inhabitants as it would be in a country with a population of just one million.

As a consequence, without additional weighting, any estimates that combine data from two or more countries would over-represent smaller countries at the expense of larger ones. The cross-national weights make an adjustment to post-stratification weights to ensure that each country is represented in proportion to the size of its in-work population. Population size adjustments are based on the most recent population figures published by Eurostat or the local statistical office (LFS, 2014; except Albania: LFS, 2013).

Cross-national weights are produced as follows:

1. Calculate  $w5 = (w4 * \text{country in-work population}) / (\text{country sample size})$
2. Calculate  $w5\_allEWCS = w5 / (\text{mean value of } w5)$

As a result of step 2, unweighted and weighted sample sizes will be identical for the whole multi-nation sample (all EWCS countries).

Population-size weights were computed for: all EWCS countries (see above), EU12 (12 first members of the EU), EU15 (15 first members of the EU), EU27 (the 27 current Member States) and EU28 (the total number of Member States at the time of the survey).

### III.2 Design effects and effective sample size

The greater the variation in inclusion probabilities and the more a sample is clustered, the less “effective” it is; this means that more interviews need to be conducted to obtain the same precision of estimates when a complex design is used as compared to simple random sampling. We can measure the loss in precision by the design effect (Kish, 1965).

For the calculation of **design effects**, we used a model-based approach that takes into account two components:

- 1) Design effect due to differential selection probabilities ( $DEFF_p$ )
- 2) Design effect due to clustering ( $DEFF_c$ )

With differing selection probabilities, the associated design effect is estimated using the following formula:

$$DEFF_p = n * \frac{\sum_{i=1}^n w1\_scaled_i^2}{(\sum_{i=1}^n w1\_scaled_i)^2}$$

In the above equation,  $w1\_scaled_i$  is the design weight associated with the  $i^{th}$  element.

In all countries, clustered sample designs were used. In such situations, there is also a design effect due to clustering, which can be calculated as follows:

$$DEFF_c = 1 + (b - 1) * \rho$$

Where  $b$  is the mean number of respondents per cluster ( $b=n/m$  where  $m$  is the number of clusters in the sample) and  $\rho$  is the intra-cluster correlation (or “rate of homogeneity”) – a measure of the extent to which persons within a clustering unit are more homogenous than persons with the population as a whole. In the calculations presented below, a default value of 0.02 was used for the intra-class correlation coefficient.<sup>14</sup>

$$DEFF_c = 1 + (b - 1) * .02$$

The total design effect is the product of the design effect due to differing selection probabilities ( $DEFF_p$ ) and the design effect due to clustering ( $DEFF_c$ ).

The **effective sample size** is an estimate of the sample size that a survey conducted using simple random sampling would have required to achieve the same precision as the complex sample (with clustering and differential selection probabilities). The effective sample size can be written as:

$$n_{eff} = \frac{n}{DEFF_p + DEFF_c}$$

An overview of design effects due to differing selection probabilities and due to clustering, and the effective sample size, is given in Table 9.

---

<sup>14</sup> This is a “default” value; in the European Social Survey, if no information is available from other surveys with similar variables, a default value of 0.02 is used to calculate the predicted design effect and predicted effective sample size.

In the EWCS5 technical report, an alternative formula to estimate the design effect was used; in this formula, the calculations are based on the final post-stratification weights (and clustering was not taken into account):

$$DEFF_w = n * \frac{\sum_{i=1}^n w4_i^2}{(\sum_{i=1}^n w4_i)^2} \quad \text{and} \quad n_{eff} = \frac{n}{DEFF_w}$$

In the above equation,  $w4_i$  is the final individual country weight associated with the  $i^{\text{th}}$  element.  $DEFF_w$  and the associated effective sample sizes are also presented in Table 9.

The design effect due to differing selection probabilities ( $DEFF_p$ ) is the smallest in Norway (1.01), Denmark (1.01), followed by Sweden (1.08), Finland (1.11) and Poland (1.14); these five countries used individual-level sampled. The largest design effects due to differing selection probabilities were observed in Ireland (1.48) and Spain (1.49).

The design effect based on the final post-stratification weights ( $DEFF_w$ , as calculated in the EWCS5 technical report) is up to 15% higher than the design effect due to differing selection probabilities, and varies between 1.06 in Norway and 1.56 in Romania (note: in the EWCS5, this design effect varied between 1.25 in Luxembourg and 1.63 in Sweden).

**Table 9: Design effects and effective sample size**

### III.3 Weighting evaluation

In this section, weighted and unweighted country-specific distributions are provided and compared. Weighting can reduce sampling, coverage and nonresponse bias; however, it can also introduce new bias if not performed correctly.

**Validating weighting targets:** For each country surveyed, a universe description based on official statistics was produced. In accordance with the variables that were used in the post-stratification weighting, the following variables are used for the universe descriptions:

- Age by sex (four age bands<sup>15</sup> within each gender);
- NUTS region;
- Industry (based on NACE Sector<sup>16</sup>);
- Occupation (8 categories based on ISCO 1-digit<sup>17</sup>).

For each of the variables, population data are readily available from Eurostat and/or from national statistical institutes. In three countries, the calculation of weights is based on regional statistics on workforce size collected more than two years preceding the fieldwork (Croatia, Ireland and Malta). However, LFS statistics on the workforce size by gender, age, occupation and activity sector, for all countries, were collected within two years preceding the fieldwork.<sup>18</sup>

**Validating unweighted/weighted samples:** For each of the target variables and countries, a comparison between the universe statistics and unweighted/weighted samples is given, using identical categories. These comparisons between universe and unweighted/weighted samples allow us to evaluate (1) the success of the sampling and interviewing, and (2) the effectiveness of the post-stratification adjustments.

#### Success of the sampling and interviewing (comparisons between universe and unweighted samples)

When comparing the universe statistics and unweighted samples, we focus on those cells for which the relative deviation is higher than 40%; this value means that a weighting factor of 1.4 (or .6) would be needed to adjust the cell to the universe statistics. Given that, during the post-stratification weighting process, a restriction not to exceed a maximum value of 1.4 was set for the post-stratification step, the cells marked in red in the tables will have been impacted by this weight restriction.

Across most countries, the number of cells for which the relative deviation is higher than 40% was small. Some deviations are observed for the age x gender distribution: in 19 countries, 60+ women were overrepresented in the unweighted sample, while 15-24 year-olds were underrepresented in 15 countries; both groups, however, represent a small part of the employed population. In nine countries, skilled agricultural, forestry and fishery workers, and plant and machine operators and assemblers were underrepresented in the unweighted sample; this underrepresentation was most notable in Romania, where 33.9% of workers are skilled agricultural, forestry and fishery workers, or plant and machine operators and assemblers (universe statistics), while in the unweighted sample, only 18.5% of respondents belonged to these occupational categories.

In Albania, a larger number of cells showed a deviation of more than 40%. Most notable is the underrepresentation of skilled agricultural, forestry and fishery workers and plant and machine operators and assemblers (in the agriculture and industry sectors) in the unweighted sample, and the overrepresentation of service and sales workers (in the sector of trade, accommodation and food services). In Albania, somewhat older data were used for the universe description (LFS 2013). According to the

---

<sup>15</sup> 15-24, 25-39, 40-59 and 60+ (Montenegro: 15-24, 25-49, 50-64 and 65+)

<sup>16</sup> Agriculture and industry; construction; transport, ICT; trade, accommodation and food service; non-public services; public services

<sup>17</sup> Armed forces occupations merged with Service and sales workers; Skilled agricultural, forestry and fishery workers merged with Plant and machine operators and assemblers

<sup>18</sup> QA# 47: Percentage of countries where the weights are based on LFS (or equivalent if not available) statistics on workforce size that have been collected within two years preceding fieldwork [Target: 100%]: 27 countries (or 90%)

national partner in Albania, the labour market has considerably changed in the past two years. Since August 2015, due to a government decision to fight tax evasion, business owners that had not yet officially registered their business (i.e. did not paid taxes and did not declare any employees), are now registering their business to avoid prosecution.

### **Effectiveness of the post-stratification adjustments (comparisons between universe and weighted samples)**

A comparison between universe statistics and weighted sample distributions shows some deviations across all countries. The fact that the weighted distributions do not exactly match the universe statistics is caused by the weight trimming strategy applied for the post-stratification weights.

A more detailed look at the differences between universe statistics and weighted sample distributions shows that there are a number of countries where the post-stratification adjustments were somewhat less effective (i.e. there are differences – of more than 2 percentage points – between the universe statistics and the weighted percentage). This is the case for countries, such as Albania, Finland, Hungary, Luxembourg, Poland, Portugal FYROM and Romania. For example, in Poland, 34.5% of workers are active in agriculture or industry (universe statistics). In the unweighted sample, 25.5% of employees indicated that they worked in these sectors; an underrepresentation of 36%. After post-stratification weighting, this category of workers represents 29.5% - which is still 5.0 percentage points below the universe statistic.

Note with the weighting evaluation tables:

- Column “Diff. unweighted vs. target (abs.)”: difference in percentage points between universe and **unweighted samples**; a positive difference means that the category is overrepresented in the sample, while a negative difference means that the category is underrepresented in the sample.
- Column “Diff. target vs. unweighted (size of weighting factor)”: relative difference between universe and **unweighted samples**; values are presented as an approximation of the weighting factor; for example, a value of 1.4 means that the category is underrepresented in the sample by 40%.
- Column “Diff. weighted vs. target (abs.)”: difference in percentage points between universe and **weighted samples**; the larger the difference the less effective the past-stratification was to balance the sample to the weighting targets.
- Column “Diff. weighted vs. target (rel.)”: relative differences - expressed as a percentage – between universe and **weighted samples**.

### **Comparisons between universe and unweighted samples – interim and final data in Finland, Sweden and Spain**

As noted above, that fieldwork in Finland, Spain and Sweden continued during the summer months; however, the impact on response rates due to this longer fieldwork period has been minor. Moreover, when comparing the unweighted interim and final samples to the universe statistics, mostly minor differences are seen between the two samples. Although interviewing during the summer months could have introduced a bias in the results, such a bias was not observed when looking at the variables used for post-stratification weighting. A more detailed analysis of the effect of seasonality on survey results in Spain is presented in the technical report.

## IV. Summary and conclusions

**No significant problems were detected with the way the EWCS6 sample was implemented across countries – i.e. the distributions across stratification categories of the net sample closely approximate the distributions of the universe (sampling plan).** In two countries, a comparison of the distribution across stratification categories of the net sample and the distribution of the universe showed larger deviations: Estonia (where a mistake appeared to have occurred in the selection of PSUs across rural and urban areas) and Ireland (where strict adherence to the 3:1 rule for sample implementation, combined with large variation in eligibility and response rates across PSUs, led to deviations between the planned and achieved sample breakdowns).

**It is clear that the sample designs we described are not equal probability designs – i.e. in most countries, there is considerable variation in design weights.** Designing samples that are self-weighting, however, might in fact not be feasible in most countries (due to several reasons – as listed in this document). As such, it is essential for the selection probabilities at each stage to be recorded so that these records can be used to calculate design weights. In the EWCS6, no problems were detected with the recording of selection probabilities.

Across most countries, **mostly minor differences were observed between universe statistics and unweighted sample distributions.** Nonetheless, **some deviations were observed for the age x gender distribution and the distribution by occupational category.** For example, in nine countries, skilled agricultural, forestry and fishery workers, and plant and machine operators and assemblers were underrepresented in the unweighted sample. Given the random nature of sampling and the fact that no significant problems were detected with the way that the EWCS6 samples were implemented, the differences between universe statistics and unweighted sample distributions can only be attributed to variations within and between countries in non-response relating to age, sex and working status. **The post-stratification adjustments were effective in reducing these differences.**
