The Centre for Longitudinal Studies (CLS) is an ESRC Resource Centre based at the Institution of Education. It provides support and facilities for those using the three internationally-renowned birth cohort studies: the National Child Development Study (1958), the 1970 British Cohort Study and the Millennium Cohort Study (2000). CLS conducts research using the birth cohort study data, with a special interest in family life and parenting, family economics, youth life course transitions and basic skills. The views expressed in this work are those of the author(s) (amend as necessary) and do not necessarily reflect the views of the Economic and Social Research Council. All errors and omissions remain those of the author(s).

This document is available in alternative formats.

#### Introduction

There has been an increasing awareness of the value of geographically linked data in social scientific research, especially since the 'GIS revolution' of the early 1990s (Longley and Batty, 1996). Spatial data can be approached from a number of directions. For example, "longitudinal studies are particularly valuable to geographers because they chart change, collect information across various domains and are spatially referenced" (Ekinsmyth, 1996: 364). On the other hand, economists, particularly those of a more heterodox bent, are beginning to appreciate the value of spatially referenced data, especially in research into the economics of education (e.g. Gibbons et al, 2013 who use the National Pupil Database to estimate the effects of neighbourhood composition on teenagers' behavioural and educational outcomes in England). Epidemiology and its associated disciplines are perhaps most consistently associated with investigating the spatial effects of the type of data collected across the different longitudinal cohort studies. For example, Christakis and Fowler (2007) used data from the Framingham Heart Study in the US to examine the spread of obesity in a large social network over 32 years while Tunstall et al (2010) used data from the Millennium Cohort Study to analyse the health outcomes of pregnant women who moved house. Two particularly fruitful fields are, firstly, the investigation of so-called 'neighbourhood effects' across a number of socio-economic domains (e.g. Lupton and Kneale (2012) used data from the 1970 British Cohort Study to investigate neighbourhood influences on teenage parenthood) and, secondly, network-based analyses of particular issues such as obesogenic environments (e.g Burgoine et al, 2014), accessibility to healthpromoting community resources (e.g. Wolch et al, 2011) and the impact of built environment (morphological) characteristics on health and well-being (e.g. Sarkar et al, 2014).

However, balancing the obvious advantages of incorporating the spatial dimension within longitudinal social scientific research, there are a number of important limitations to be borne in mind when dealing with this type of data. The principal consideration is protecting the identity of cohort members, particularly in the current era of 'open data' and increasing linkage of previously disparate administrative datasets. It is recognised that there is a cultural dimension to the issue of data confidentiality, with, for example, Scandinavian countries taking a more laissez-faire approach, adopting the perspective that data gathered using public funds should be available for public consumption. More socially conservative states like the US and UK, on the other hand, have tended to take a much more protectionist approach to personal data (Exeter et al, 2014). At present, the UK Data Archive takes the approach that access to geo-referenced data below Government Office Region (GOR) level should be subject to increasing access restrictions the more likely the data is to reveal the identity of cohort members. Other limitations include non-uniformity of geo-identifiers used across different sweeps of the various cohort studies and varying levels of accuracy in terms of the geo-identifiers collected (a particular problem of early sweeps before the standardisation of unit postcodes).

#### Data and methodology

In order to enable the process of spatial analysis of longitudinal cohort study data, unit postcodes are gathered from the addresses collected during interview, which are then validated by the CLS Cohort Maintenance Team using a range of specialist software products

from AFD¹. This postcode data is then used to generate point data, usually within a GIS. There are a number of licensed and open source GIS packages available (e.g. ArcGIS², MapInfo³ and QGIS⁴). The primary data source for spatialising longitudinal cohort study data within this software is the ONS Postcode Directory, available from the UK Data Service Census Support website⁵. This dataset has been released quarterly since 2004 (every February, May, August and November) and contains Ordnance Survey eastings and northings for each unit postcode centroid. These eastings and northings are spatialised in GIS in the form of 'x', 'y' points, usually to an accuracy of 1 metre of the mean postcode centroid⁶. Areal (polygon) representations of unit postcodes are produced in the OS 'Code-Point with Polygons' product, available from Edina Digimap³. The current (November 2014) release of the Postcode Directory contains some 42 different geographies dating back to 1991, encompassing Census, health, administrative, environmental and educational domains. Once again, boundaries for the majority of these geographies are available from Edina Digimap.

The point-based longitudinal cohort study data is associated with these geographies by means of a 'field join' (usually based on unit postcode) or by a 'spatial join' (i.e. based on location) within a GIS. One drawback of the use of mean unit postcode centroids in georeferenced data is their wide variation in size (typically unit postcodes in rural areas will cover a much larger extent than their urban counterparts). This means that greater accuracy will be achieved in geo-referencing the address at interview of cohort members who live in more urbanised areas. Recent developments in geo-coding with products such as OS 'AddressBase'<sup>8</sup> mean that it is possible to create point data based on the grid references of individual properties/locations (thus with an accuracy of metres rather than tens/hundreds of metres achieved using unit postcode centroids). This is particularly important for the types of network and accessibility based analyses alluded to above, as well as specific types of environmental analysis, such as the impact on residents of the electromagnetic fields of high voltage overhead power lines (e.g. Swanson et al, 2014).

#### Extent and nature of the data

England and Wales use the same naming conventions across different geographies. Post-devolution, Scotland has adopted slightly different naming conventions. For example, in both 2001 and 2011 Census geography, what are known as 'Lower Super Output Areas' and 'Middle Super Output Areas' in England and Wales are called 'Data Zones' and 'Intermediate Geographies' respectively in Scotland and the mean populations used to create these areal units also varies between E&W and Scotland<sup>9</sup>. The projected coordinate system used to display geo-referenced data across Great Britain (i.e. England, Wales and Scotland) is the

<sup>&</sup>lt;sup>3</sup> Licensed software, available from <a href="http://www.mapinfo.com/">http://www.mapinfo.com/</a>

<sup>&</sup>lt;sup>4</sup> Open-source software, available from http://www2.qgis.org/en/site/

<sup>&</sup>lt;sup>5</sup> http://census.edina.ac.uk//pcluts.html

<sup>&</sup>lt;sup>6</sup> There are, however, a range of 'grid reference positional quality indicators', ranging from 1 ('within the building of the matched address closest to the postcode mean' to 9 ('no grid reference available'). Some 85% of all postcodes have a positional quality indicator of 1.

<sup>&</sup>lt;sup>7</sup> http://digimap.edina.ac.uk/digimap/home

<sup>8</sup> http://www.ordnancesurvey.co.uk/business-and-government/products/addressbase-products.html

<sup>&</sup>lt;sup>9</sup> For example, the mean population of a 2011 LSOA is 1,500 whereas the mean population of a 2011 DZ is 808.

British National Grid<sup>10</sup>. The range of Ordnance Survey products (e.g. MasterMap, AddressBase, OpenData) is available for Great Britain (i.e. excluding Northern Ireland).

Northern Ireland uses its own equivalent to the ONS Postcode Directory, called the Central Postcode Directory<sup>11</sup>, and the process of spatialising geo-referenced data works in exactly the same way as with Great Britain data. Northern Ireland uses a different projected coordinate system from the rest of the UK, the Irish National Grid<sup>12</sup>.

#### **Availability of Datasets**

Because of the potentially disclosive nature of these datasets, geographic identifiers below Government Office Region (GOR) are being released under Secure Access<sup>13</sup>; these are listed at Appendix A.

Appendix B lists the contents of the Secure Access Datasets.

Appendix C lists the geographies available on the Datasets available under the standard End User Licence.

As you will note in Appendix C, there are two versions of MCS5 and MCS6 geographically linked data available, one set based on 2001 Census boundaries and the other set based on 2011 Census boundaries. Due to the potential for identification of a small number of individual cohort members (i.e. those located in 'slivers' between those areal units whose boundaries changed between 2001 and 2011), users can choose either, <u>but not both</u>, of these datasets.

#### **Further Information**

If you have any queries, please contact us at <a href="mailto:clsfeedback@ioe.ac.uk">clsfeedback@ioe.ac.uk</a> or view our website at http://www.cls.ioe.ac.uk.
