Preface

CLOSER (Cohort & Longitudinal Studies Enhancement Resources) aims to maximise the use, value and impact of longitudinal studies, both at home and abroad. Bringing together eight leading studies, the British Library and the UK Data Service, CLOSER works to stimulate interdisciplinary research, develop shared resources, provide training, and share expertise. In this way CLOSER is helping to build the body of knowledge on how life in the UK is changing – both across generations and in comparison to the rest of the world.

CLOSER's research includes a number of work packages focused on retrospective harmonisation, their aim being to make the data from different longitudinal studies more comparable in order to find out how life in the UK is changing from generation to generation. This documentation describes a dataset produced as part of the CLOSER harmonisation work package on childhood environment variables of potential relevance to wellbeing in later life.

Acknowledgements

We would like to thank David Bann, Rebecca Hardy, Catharine Gale and Alissa Goodman for providing advice and expertise throughout the project. We would also like to thank Claire Crawford and Brian Dodgeon for their work in harmonising the childhood and adult social class measures and parental education as part of the CLOSER Work Package 2, which we used as part of this project.

CLOSER would like to thank the studies for providing the data and the participants of the longitudinal studies included in this harmonisation project for taking part over many years and making this research possible.

Dataset production

The dataset was constructed by Natasha Wood and Mai Stafford while based at UCL, with additional processing and metadata harmonisation by Dara O'Neill at CLOSER.

Introduction

This CLOSER interdisciplinary project used data from the MRC National Survey of Health and Development (NSHD), the 1958 National Child Development Study (NCDS) and the 1970 British Cohort Study (BCS70) to address the following questions:

- i) Is father's social class associated with mental wellbeing in adulthood?
- ii) Is the childhood environment conceived more broadly on multiple domains (family socio-economic disadvantage, impaired child-rearing and parenting, family instability, and poor parental health) associated with adult mental wellbeing, and are associations explained by poor childhood health?
- iii) Are correlations between these material and psychosocial domains consistent in each of the studies?

This project identified measures of the childhood socio-economic and psychosocial environment that may be of relevance to mental wellbeing in adulthood across three national birth cohort studies. The aim was to collate or derive variables from childhood which were comparable across the three studies in order to test their prospective association with later wellbeing.

These datasets formed the basis of an article by Wood et al. (2017), in conjunction with data harmonised as part of CLOSER Work Package 2.

Studies included

- 1946 MRC National Survey of Health and Development (NSHD)
- 1958 National Child Development Study (NCDS)
- 1970 British Cohort Study (BCS70)

Methods

In creating the measures of the childhood environment, the following approach was taken. Firstly, the literature on childhood risk factors for poor mental health and mental wellbeing in adulthood was used to identify relevant domains of the childhood environment. Five domains of the childhood environment were identified: socio-economic, child rearing and parenting, family instability, parental health, and antenatal/perinatal problems. We considered that these captured circumstances that were "external" to the child. Factors such as childhood cognition, illness and mental health may be influenced by earlier childhood circumstances and are arguably on the explanatory pathway linking the childhood environment to later mental wellbeing and they were not the main focus of this study.

Once the childhood environment domains had been identified the most relevant variables were found on each study. We recognised the limits of retrospective harmonisation across all these childhood environment domains. Our aim was to identify variables that capture similar constructs for each of these domains and take a coordinated analytical approach to maximise comparability across the studies.

When assessing comparability of measures across the studies we looked at who answered the question (i.e. a study member, a parent, a teacher or a health visitor), the age of the study member when the measure was collected, as well as the question wording. In most instances we used the original questions, but we also used previously derived variables and did not go back to the original data if the derived measure was suitable. Variables were derived which had the same categories across the studies, where possible. When data were collected on the same measure at multiple sweeps in childhood we derived the mean across the sweeps or counted the number of sweeps in a particular level of exposure.

Sample selection

No exclusions were made.

Data cleaning

Overall there was very little data cleaning which needed to be carried out as we used cleaned variables provided by the studies for the harmonised variable derivations. In some instances, missing data were substituted with observations from earlier or later sweeps. Where this has been done a flag has been created to show that the observation was missing and has been substituted with available data. All missing data were coded up as either missing data due to sweep non-response, or missing data due to item non-response.

Limitations

Differences between the studies included question wording, different ages when the measures were collected and differences in who answered the question. Some childhood measures were based upon parental assessments, while some were teacher or health visitor assessments, or were obtained from school records. For example, absence from school was based upon administrative data from school records plus parental self-reports in NSHD. In NCDS and BCS70, school absence is based upon parental self-reports alone. Whilst short-term as well as longer-term separation from mother was captured in the NSHD and the NCDS, in the BCS70 the question refers only to long-term and more permanent separation.

Given improvements in housing conditions across the 20th century, some measures were not applicable in BCS70. For example, in BCS70 lack of hot water in accommodation was not asked about at ages 10 and over and therefore it was assumed when creating the lack of household amenities derived variable for the

BCS70 that all study members had access to hot water. Additionally, two measures were reported retrospectively in adulthood (both parent-child relationship measures in NSHD), although the majority were prospective.

These differences are noted for the individual measures in the documentation which follows. Where there were differences in the measures which meant that they could not be harmonised standardised measures were also derived using z-score transformation to aide comparison across the three studies. The standardised variables are identified by “z” at the end of the variable name and are described in the documentation.

Quality Assessment

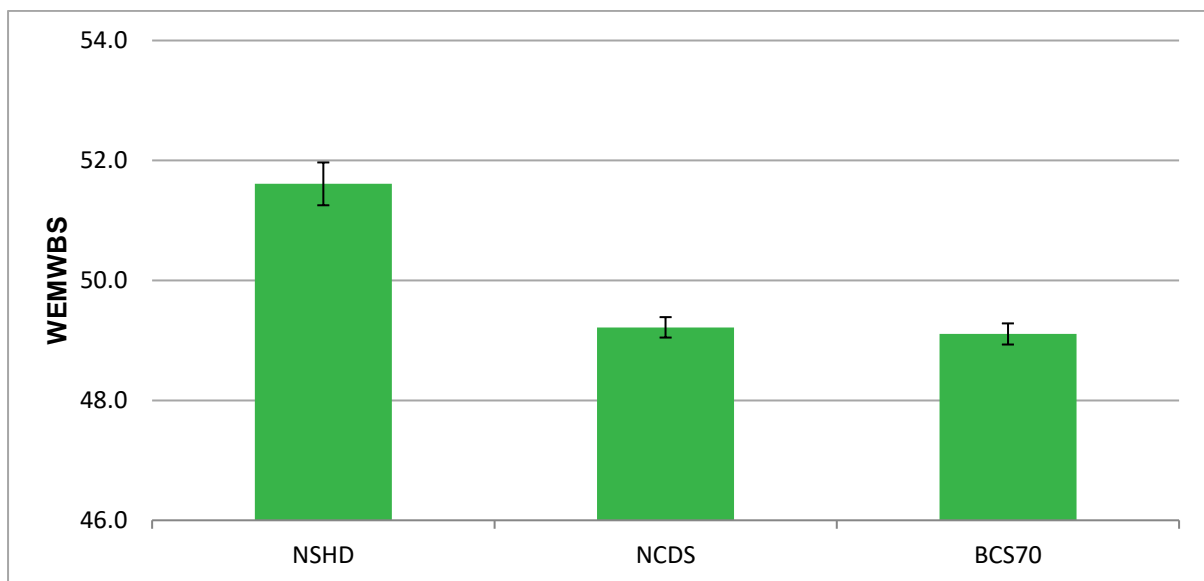

This section presents some of the findings on childhood environment and adult mental wellbeing cross the three studies.

Mental wellbeing in adulthood

Adult mental wellbeing was measured using the Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS) in all three studies. WEMWBS is a validated instrument which measures both the eudemonic and hedonic aspects of wellbeing (Tennant et al., 2007) and comprises 14 items on a 5-point Likert scale which are totalled to give a score ranging from 14 to 70, with 70 reflecting higher levels of wellbeing. Wellbeing was measured at age 60-64 years in NSHD, age 50 in NCDS and age 42 in BCS70.

Figure 1 shows that mean wellbeing was higher in NSHD (mean=51.6, SD=8.3) than in NCDS (49.2, 8.1) or BCS70 (49.1, 8.3). These differences may be due to age and/or cohort effects.

Figure 1: Wellbeing across the studies

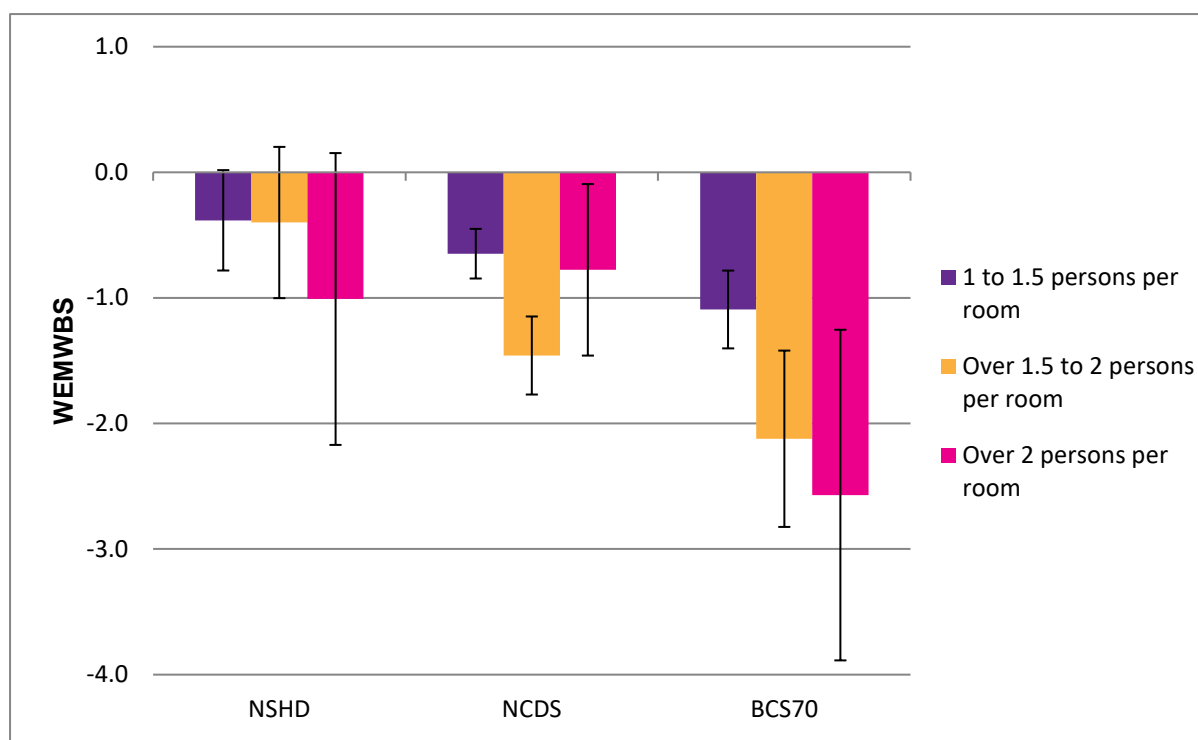

Adjusted for sex.

In summary, we found that childhood socio-economic disadvantage was strongly associated with poorer mental wellbeing in adulthood in BCS70, but this association was weaker in the other two studies. We also found that poorer quality of the parent-child relationships and poor parental mental health were strongly associated with poorer mental wellbeing in all three studies. This finding was consistent despite some differences in the measures. We also examined associations between childhood socio-economic disadvantage and parent-child relationships. These results are illustrated below.

Overcrowding in childhood and adult mental wellbeing

Figure 2 shows the mean sex-adjusted difference in wellbeing by overcrowding in the three studies. There were differences among the studies in the extent to which overcrowding in childhood was associated with adult mental wellbeing with the association being stronger among the later born cohorts. In NSHD, there was not a clear association between experiencing overcrowding in childhood and adult mental wellbeing, whilst in NCDS there was some association with those who lived in more overcrowded conditions having poorer mental wellbeing in adulthood than those who lived in accommodation where there was only one person per room. However, in the BCS70 there was a strong association between overcrowding in childhood and adult mental wellbeing, with those who lived in the most crowded conditions experiencing considerably lower levels of adult mental wellbeing compared to those who did not live in crowded conditions.

Figure 2: Adult mental wellbeing by number of occasions lacked household amenities in childhood

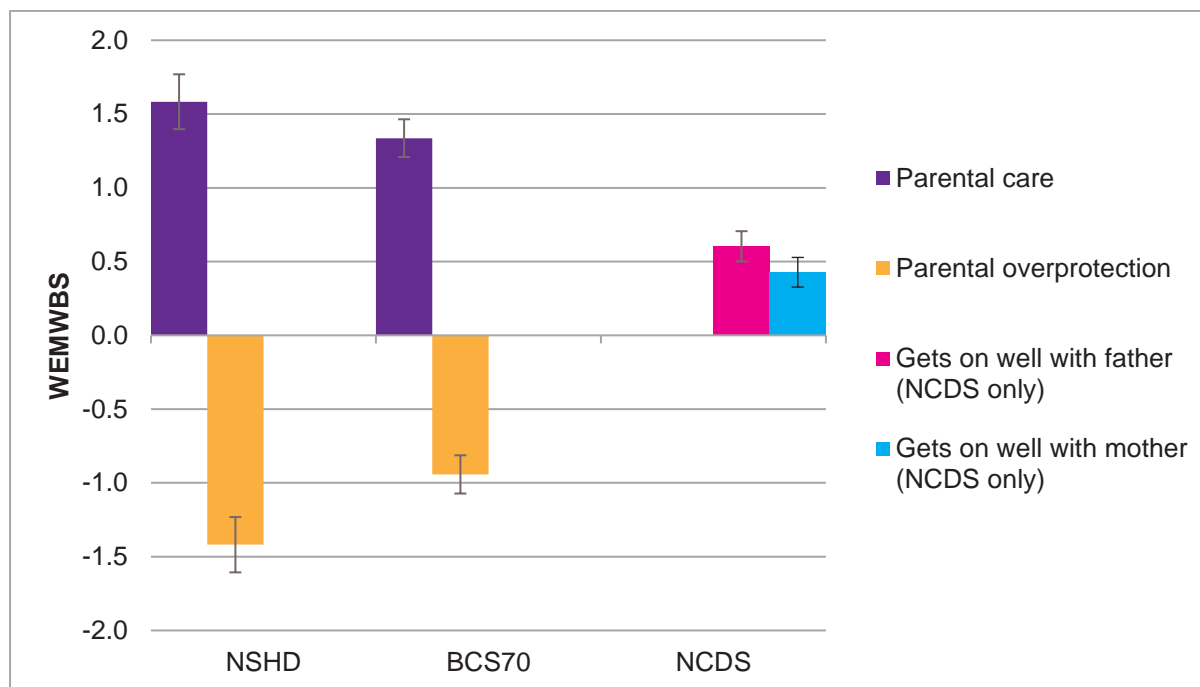

Reference category: up to 1 person per room. Adjusted for sex.

Parent-child relationships and adult mental wellbeing

Figure 3 shows the differences in adult mental wellbeing by parent-child relationships. NSHD and BCS70 measured parental care and overprotection using the Parental Bonding Instrument (Parker, Tupling, & Brown, 1979). NCDS did not use the parental bonding instrument and instead measures of how well the study member got on with their parents were used. In all three studies, there was an association between parental-child relationship quality and adult mental wellbeing. In NSHD and BCS70, those whose parents were more caring and less overprotective had higher levels of adult mental wellbeing than those whose parents were less caring and more overprotective. Similarly, in NCDS, those who said they got on well with their father or their mother had higher levels of adult mental wellbeing than those who did not get on with their parents.

Figure 1: Adult mental wellbeing by parent-child relationships

For NSHD and BCS70, the parental care scale runs from 'low parental care' to 'high parental care' and the overprotection scale runs from 'low parental overprotection' to 'high parental overprotection'. For NCDS only, the most comparable scale runs from 'doesn't get on well with parent' to 'gets on well with parent'. Estimates have been standardised. Adjusted for sex.

Father's social class and parent-child relationships

Figure 4 shows parent-child relationships by father's social class. Father's social class was measured in ridit scores, a technique which takes account of the population distribution across social class categories, enabling comparison over time (Mackenbach & Kunst, 1997). The graph shows the difference in parent-child relationship quality between those whose fathers were in the highest social class compared to those whose fathers were in the lowest social class.

In two of the studies, there was a positive social gradient in the association between father's social class and parent-child relationship quality. In BCS70, those whose fathers were in the most advantaged social class perceived their parents to be more caring (and less overprotective; data not shown here) than those whose fathers were in the least advantaged social class. In NCDS, those whose fathers were in the most advantaged social class were more likely to get on well with their fathers than those whose fathers were in the least advantaged social class, but in this cohort, there was no association between father's social class and how well the study member got on with their mother. In NSHD, there was no association between father's social class and parent-child relationships.

Figure 4: Parent-child relationships by father's social class

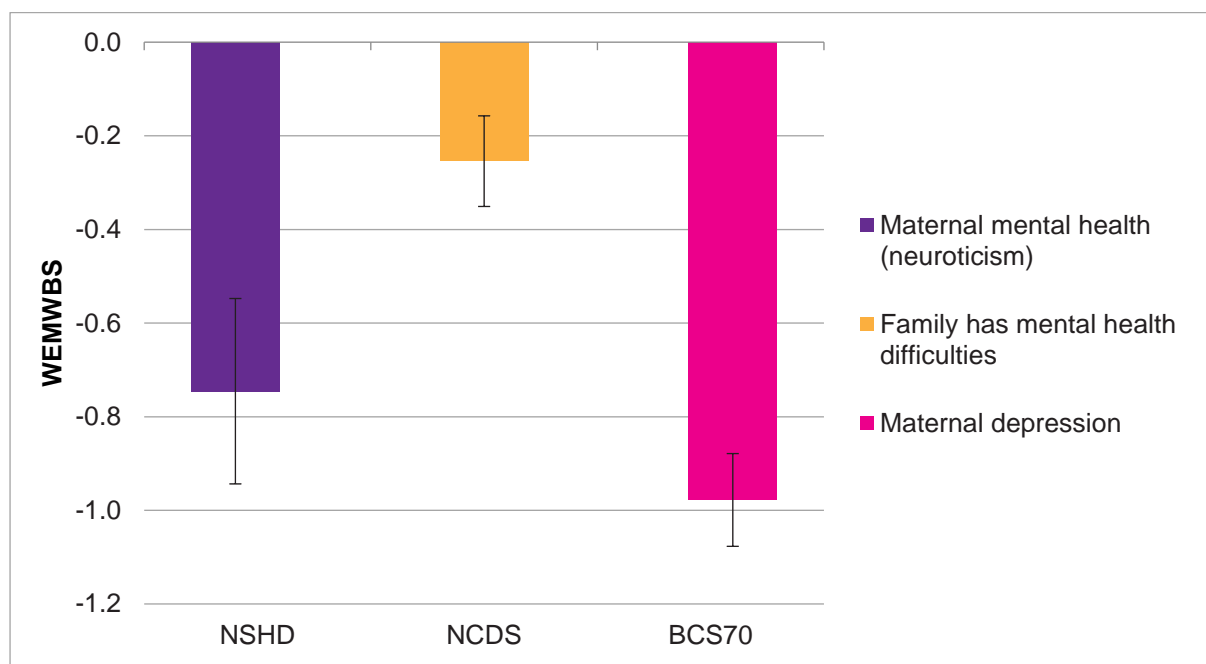

Reference category: Lowest father's social class (ridit score). Higher scores indicate a more positive social gradient. For NSHD and BCS70, the parental care scale runs from 'low parental care' to 'high parental care'. For NCDS only, the scale runs from 'does not get on well with parent' to 'does get on well with parent'. Estimates have been standardised. Adjusted for sex.

Parental mental health and adult mental wellbeing

Figure 5 shows adult mental wellbeing by maternal or family mental health. Each of the studies measured maternal or family mental health differently and therefore are not equivalent, but across all three studies those whose parents experienced poorer mental health during childhood also reported lower mental wellbeing in adulthood. There were differences in the strength of the association across the studies with a stronger association between parental mental health and adult mental wellbeing in NSHD and BCS70 than in NCDS.

Figure 5: Adult mental wellbeing by parental mental health

Coefficients are standardised. Adjusted for sex. In NSHD, maternal mental health was measured by the Maudsley Personality Inventory (Jensen, 1958). In NCDS health visitors assessed whether the family had mental health difficulties. In BCS70, mother's depression was measured using the malaise inventory (Rutter & Whitmore, 1970).

Harmonised variables description and source

This section details how the measures of the childhood environment were derived across the following domains:

- family socio-economic position;
- child rearing and parenting;
- family instability;
- parental health;
- child health; and
- wellbeing.

In our analyses, we also used father's social class and parental education. However, these variables are not included in this user guide as they are part of CLOSER work package 2 and are described within that documentation.

Family socio-economic position

Harmonised variable		
Variable name	crowd	
Variable description	Crowding in childhood - persons per room	
Description of derivation	Whether the study member experienced overcrowding in childhood, which is measured as the number of persons per room. The measure is a median score of overcrowding collected at different points between birth and age 11 in the NSHD and the NCDS, but in the BCS70 overcrowding was only collected at 5 years of age. For any cases in NSHD and NCDS which were missing data from one or more sweeps, the measure was derived using the sweeps where data was available.	
Variable code list	1	Up to 1
	2	Over 1 to 1.5
	3	Over 1.5 to 2
	4	Over 2
	-999	Missing value - item non-response
	-111	Missing value - non-response to sweeps
Source variables		
Study	Age(s)	Variable name(s)
NSHD	Birth, 2, 4, 6, 8, & 11 years	CROW46 CROW48 CROW50 CROW52 CROW54 CROW57

NCDS	Birth, 7, & 11 years	n512 n607 n1683
BCS70	5 years	e228b

Harmonised variable

Variable name	ameni	
Variable description	Number of occasions childhood accommodation lacked sole use of amenities - bath, hot water, kitchen	
Description of derivation	The derived variable captures whether the study member's family lacked access to each amenity (either sole use of a bath, a kitchen or hot water) in early childhood and at age 10/11. N.B. at age 10 in the BCS70, hot water was not included as one of the amenities, therefore it is assumed that everyone had access to hot water. If there was missing data at one age, then the measure was derived just using the data which was present at the other age. A flag amenimiss was created to show which cases this affected.	
Variable code list	0	No occasions
	1	1 occasion
	2	2 occasions
	-999	Missing value - item non-response
	-111	Missing value - non-response to sweeps

Source variables

NSHD	2 & 11 years	aml48 aml57
NCDS	7 & 11 years	n621 n1681
BCS70	5 & 10 years	e221 e224 e226 d3.1 d3.2

Harmonised variable

Variable name	tenure	
Variable description	Accommodation owned or rented in childhood	
Description of derivation	This variable captures whether the study member was in rented or owned accommodation in early childhood and at age 10/11. This variable does not distinguish between accommodation rented privately and rented from the council.	
Variable code list	1	Rented at both time points
	2	Owned at one time point
	3	Owned at both time points
	-999	Missing value - item non-response

	-888	Don't know
	-111	Missing value - non-response to sweeps
Source variables

NSHD	2 & 11 years	own48 own57
NCDS	7 & 11 years	n200 n1152
BCS70	5 & 10 years	e220 d2

Harmonised variable		
Variable name	teenm	
Variable description	Had a teen mother at birth	
Description of derivation	Using the age of the mother when the study member was born. All those mothers under the age of 20 were identified as a teen mother.	
Variable code list	0	No
	1	Yes
	-999	Missing value - item non-response
	-111	Missing value - non-response to sweep

Source variables		
Study	Age(s)	Variable name(s)
NSHD	Birth	MAB46
NCDS	Birth	n553
BCS70	Birth	bd1mage

Harmonised variable		
Variable name	teenf	
Variable description	Had a teen father at birth	
Description of derivation	Using the age of the father when the study member was born. All those fathers under the age of 20 were identified as a teen father.	
Variable code list	0	No
	1	Yes
	-999	Missing value - item non-response
	-222	Not applicable - no father (<i>BCS70 only</i>)
	-111	Missing value - non-response to sweep

Source variables		
Study	Age(s)	Variable name(s)
NSHD	Birth	PAB46
NCDS	Birth	n494
BCS70	Birth	bd1fage

Child rearing and parenting

Harmonised variable		
Variable name	brfed	
Variable description	Whether breastfed	
Description of derivation	Details on whether the study member was breastfed collected between ages of 2 to 7 years. The details were given by the mother.	
Variable code list	1	Not breastfed
	2	Breastfed for under 1 month
	3	Breastfed for over 1 month
	-999	Missing value - item non-response
	-888	Don't know
	-111	Missing value - non-response to sweep
Source variables		
Study	Age(s)	Variable name(s)
NSHD	2 years	BRE
NCDS	7 years	n222
BCS70	5 years	e020

Harmonised variable		
Variable name	parint	
Variable description	Parental interest in child's education	
Description of derivation	This variable measures how interested parents were in the study member's education. In NCDS and BCS70 the question was asked separately for the mother and for the father, but in the NSHD it was asked for both parents. To make the measure comparable with NSHD, the interest of the parent who was most interested in their child's education was used in NCDS and BCS70. If either parent in NCDS or BCS70 were missing data, then the response of the parent which had data was used.	
Variable code list	1	Very interested
	2	Some interest
	3	Little interest
	-999	Missing value - item non-response
	-888	Don't know

	-111	Missing value - non-response to sweep
Source variables		
Study	Age(s)	Variable name(s)
NSHD	11 years	TINT57
NCDS	7 years	N43 N44
BCS70	10 years	J097 J098

Harmonised variable	
Variable name	carenshd (NSHD only) carebcs (BCS70 only)
Variable description	Parental care (average across both parents), NSHD Parental care, BCS70
Description of derivation	N.B. there is no equivalent measure in the NCDS, and while comparable, the measures in NSHD and BCS70 cannot be deemed directly equivalent. Both the NSHD and the BCS70 contained a version of the parental bonding instrument (Parker et al., 1979), but the measures were slightly different on each study. The parental bonding instrument included in NSHD covered the quality of the relationship with each parent in the first 16 years of life and was asked retrospectively to the study member at age 43. The parental bonding instrument was included in BCS70 at age 16 and asked about both parents together. Two subscales were derived (Rodgers, 2009) – parental care and parental overprotection. There were 11 items capturing maternal care and 11 capturing paternal care in the NSHD and 7 items capturing parental care in the BCS70. All the parental care items in the parental bonding instrument were totalled to give a continuous measure which was then standardised. The parental care measures were averaged across both parents in NSHD. If one parent was missing data then the variable was derived just using the data which was available from the other parent. A flag, carenshdmiss , shows which cases were missing data from one or both parents. Standardised versions of the variable were derived using z-score transformations, and the variables stored as carenshdz and carebcsz .

Variable range & code list	<i>Unstandardised:</i> 0 (not caring) to 33 (very caring) <i>Standardised:</i> -3.73 to 1.501	NSHD
	<i>Unstandardised:</i> 0 (not caring) to 7 (very caring) <i>Standardised:</i> -2.647 to 1.154	BCS70
	-999	Missing value - item non-response
	-111	Missing value - non-response to sweep

Harmonised variable

Variable name	overnshd (<i>NSHD only</i>) overbcs (<i>BCS70 only</i>)
Variable description	Parental overprotection (average across both parents), NSHD Parental overprotection, BCS70
Description of derivation	See description for <i>carenshd</i> and <i>carebcs</i> . N.B. there is no equivalent measure in the NCDS. While comparable, the measures in NSHD and BCS70 cannot be deemed directly equivalent. The parental overprotection scale was derived from 13 items in NSHD and 4 items in BCS70. All the parental overprotection items in the parental bonding instrument were totalled to give a continuous measure which was then standardised. The parental overprotection measures were averaged across both parents in NSHD. If one parent in NSHD was missing data, then the variable was derived just using the data which was available from the other parent. A flag overnshdmiss

	shows which cases were missing data from one or both parents in NSHD. Standardised versions of the variable were derived using z-score transformations, and the variables stored as overnshdz and overbcsz .

Family instability

Harmonised variable															
Variable name	divorce														
Variable description	Parents divorced during study member's childhood														
Description of derivation	In NSHD, <i>divsbc</i> , which had been derived from interviews with the respondent at each childhood sweep, was used to identify if parental divorce occurred before the participant reached the age of 16. <i>Divsbc</i> measured whether parents had got divorced and what age the study member was. In NCDS and BCS70, a number of variables which collected information on change of circumstances since previous sweep and whether parental divorce was the cause were collated across multiple sweeps in childhood and were used to create the divorce variables. In both NCDS and BCS70, study members were also asked in adulthood whether their parents divorced and what age they divorced; if study members said that their parents divorced by the time they were 16 years old then they were set to divorced.														
Variable code list	<table border="1"> <tr> <td>0</td> <td>Not divorced</td> </tr> <tr> <td>1</td> <td>Divorced</td> </tr> <tr> <td>-999</td> <td>Missing value - item non-response</td> </tr> <tr> <td>-888</td> <td>Don't know</td> </tr> <tr> <td>-333</td> <td>Not applicable - parents never lived together (<i>BCS70 only</i>)</td> </tr> <tr> <td>-222</td> <td>Parent died / never lived with parents (<i>NCDS & BCS70</i>)</td> </tr> <tr> <td>-111</td> <td>Missing value - non-response to all sweeps</td> </tr> </table>	0	Not divorced	1	Divorced	-999	Missing value - item non-response	-888	Don't know	-333	Not applicable - parents never lived together (<i>BCS70 only</i>)	-222	Parent died / never lived with parents (<i>NCDS & BCS70</i>)	-111	Missing value - non-response to all sweeps

Harmonised variable											
Variable name	sepmum (NSHD & NCDS) sepmumbcs (BCS only)										
Variable description	Ever separated from mother										
Description of derivation	Each of the studies collected information on whether the study member had ever been separated from their mother. In NSHD and NCDS, it included shorter term separation (e.g. one week or more) as well as long term separation, whilst in BCS70, it referred only to long-term separation including permanent separation from mother. For this reason, there are greater numbers in NSHD and NCDS reporting separation from mother than in BCS70. The BCS70 measure is in a separate derived variable as it is not equivalent to the NSHD and NCDS measures.										
Variable code list	<table border="1"> <tbody> <tr> <td>0</td> <td>Never separated or separated for under one week (<i>NSHD & NCDS</i>) No (<i>BCS70 only</i>)</td> </tr> <tr> <td>1</td> <td>Separated for one week or more (<i>NSHD & NCDS</i>) Yes (<i>BCS70 only</i>)</td> </tr> <tr> <td>-999</td> <td>Missing value - item non-response</td> </tr> <tr> <td>-888</td> <td>Don't know</td> </tr> <tr> <td>-111</td> <td>Missing value - non-response to sweep</td> </tr> </tbody> </table>	0	Never separated or separated for under one week (<i>NSHD & NCDS</i>) No (<i>BCS70 only</i>)	1	Separated for one week or more (<i>NSHD & NCDS</i>) Yes (<i>BCS70 only</i>)	-999	Missing value - item non-response	-888	Don't know	-111	Missing value - non-response to sweep

Variable name	resmove	
Variable description	Number of residential moves in childhood	
Description of derivation	Each of the studies collected information on the number of residential moves which had been experienced in childhood. In NSHD, information was collected from age 2 to 15. In NCDS, information was collected at age 16 about all residential moves from birth to age 16. In BCS70, residential moves were collected at age 10 about the number of addresses lived at since birth for 6 months or more. Each original variable on the 3 studies was derived into comparable categories.

BCS70	10 years	a11.1

Parental health

Harmonised variable

Variable name	hprobmoth	
Variable description	Mother had a health problem	
Description of derivation	Information on whether parents had any health conditions was collected on each of the studies, but there were differences among the studies in how the information was collected. In NSHD and NCDS, the study member's parents were asked, when the study member was age 15 and age 11 respectively, whether each parent had any health conditions from a given list. There were some differences in the health conditions	

	<p>which were listed. In NSHD, the conditions comprised asthma, eczema, hay fever, chronic cough, rheumatism in joints, anaemia, nervous conditions, heart trouble, kidney trouble and any other conditions. In NCDS, the health conditions comprised respiratory conditions, psychiatric conditions, educationally subnormal (ESN), urogenital, alimentary, locomotor, neurological, infectious, special senses, cardiovascular, dermatological and any other condition. If the parent had any of the listed conditions in NSHD and NCDS, they were categorised as having a health condition. In BCS70, the measure did not list particular health conditions; instead parents were asked when study member was 10 years old whether they had had an illness since the study member was 5 years old.</p>

Harmonised variable		
Variable name	mnhns hd (NSHD only) mnhbcs (BCS70 only)	
Variable description	Mother's mental health (Maudsley Personality Inventory - neuroticism scale only), NSHD Mother's mental health (Total malaise score), BCS70	
Description of derivation	<p>In NSHD, when the study members were age 15, their mothers rated their own mental health using the Maudsley Personality Inventory (Jensen, 1958), which comprised 6 items measuring neuroticism. The scale on this runs from 0 to 6 with 0 reflecting low neuroticism and 6 reflecting high neuroticism.</p> <p>In BCS70, when the study members were age 10, their mothers were asked a series of questions which measured their own malaise using a 24-item malaise inventory (Rutter & Whitmore, 1970; Rodgers, Pickles, Power, Collishaw, & Maughan, 1999). The 24 items were scored from 0 to 100 with 0 reflecting seldom or never and 100 most of the time. The 24 items were added together to create a continuous scale from 1 to 2154, with a higher score reflecting higher levels of depression.</p> <p>For both studies, standardised versions, mnhns hdz and mnhbcsz, were subsequently derived using z-score transformations.</p>

Harmonised variable		
Variable name	prmnh	
Variable description	Poor maternal / familial mental health	
Description of derivation	This is derived from the maternal/familial mental health variables described already (<i>mnhnshd/bcs and famill</i>). For BCS70, <i>prmnh</i> is derived by dichotomisation of the source variable at the 3% cut point to reflect poor mental health, to be equivalent with NCDS, where 3% of families had poor mental health. For NSHD, dichotomisation was also performed, with values of 6 on the source scale deemed indicative of poor mental health.

NCDS	Birth	n646
BCS70	Birth	a0278

Harmonised variable		
Variable name	schabs	
Variable description	Length of time absent from school due to illness	
Description of derivation	On all three studies there were measures of school absence due to ill health; however, it was collected differently across the three studies. In NSHD, the data came from school administrative records, which recorded any absences due to ill health from age 6 to age 10. In NCDS and BCS70, parents were asked how long the study member had been away from school due to ill health in the past 12 months. Consequently, there could be some misreporting in NCDS and BCS70 compared to NSHD.	
Variable code list	1	Less than 1 week

BCS70	10 years	b22.1

Harmonised variable	
Variable name	intnshd (NSHD only) intncds (NCDS only) intbcs (BCS70 only)
Variable description	Internalising behaviour in childhood
Description of derivation	<p>NSHD collected information from teachers on internalising disorder in childhood, using the Pintner Aspects of Personality Inventory, which provides a measure of the child's personality along the dimensions of neuroticism and extroversion/introversion (Pintner & Forlano, 1938; Pintner, Loftus, Forlano, & Alster, 1937). Items which measure internalising symptoms were identified using factor analysis (Xu, 2013). NCDS and BCS70 collected data on symptoms of affective disorder (including both internalising and externalising behaviours) at age 16 using the Rutter scale (Rutter, 1967). There were differences in the scale between NCDS and BCS70. The NCDS Rutter scale comprised more items than did BCS70 (26 items compared to 19). In NCDS, the scale was rated by teachers, whilst in BCS70 it was rated by parents, at age 16. To maximise comparability with NSHD, the items in the scales in NCDS and BCS70 were separated out into those which measured internalising behaviours and those which measured externalising behaviours using factor analysis. Details of the factor analysis is provided in the appendices (Appendix 1). While comparable, the internalising variable cannot be deemed directly equivalent across the studies and so has been labelled differently for each study.</p> <p>Standardised versions of the variable were derived using z-score transformations, and the variables stored as intnshdz, intncdsz, and intbcsz.</p>

Wellbeing

Harmonised variable	
Variable name	totwemwbs
Variable description	Total WEMWBS score
Description of derivation	On each of the studies, the Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS), a validated instrument (Tennant et al., 2007) which measures both hedonic and eudemonic elements of wellbeing, was collected. The WEMWBS scale comprises 14 items and these have been added up to form a score ranging from 14 (low wellbeing) to 70 (high wellbeing). On each of the studies, WEMWBS was collected in a self-completion questionnaire.
	14 to 70 Continuous scale

NCDS	18,558	ncds_closer_wp9	End user licence
BCS70	19,050	bcs70_closer_wp9	End user licence

Licencing

All datasets are available from the UK Data Service (UKDS) at <https://www.ukdataservice.ac.uk/get-data/key-data/cohort-and-longitudinal-studies>.

All users of the data need to be registered with the UKDS (details of how to do this are available at <https://www.ukdataservice.ac.uk/get-data/how-to-access/registration>).

Data under the End User Licence can be downloaded once the access conditions have been ticked. Data under the Special Licence will need to request permission and complete a form. Once that has been accepted the data will be available to download.

Linkage to other data from a study

The datasets are linkable to other data released by CLOSER using the CLOSER Serial Number ('closerid') variable. This is a pseudonymised participant identifier that is included in all datasets from the CLOSER harmonisation work packages.

If you wish to link the harmonised data to other data from NCDS and BCS70, the original participant identifiers from these studies are also included in the harmonised datasets for those studies.

If you wish to link other NSHD data to the harmonised dataset for that study, contact NSHD at: <https://skylark.ucl.ac.uk/NSHD/doku.php>.

Dataset structure

Variable name	Label	Format	Values	Note
closerid	CLOSER ID	string (8)		
ncdsid/bcsid	NCDS serial number/BCS70 research case identifier	string (7)		In the case of NSHD, requests for the original participant identifiers should be directed to the studies themselves
stid	Study identifier	string (10)	NSHD / NCDS / BCS70	Note this has been kept as string to avoid divergences in how studies are encoded across CLOSER work packages (as these may comprise different sets of studies)

totwemwbs	Total WEMWBS score	numeric		

Appendix 1

Factor analysis for internalising and externalising symptoms in childhood in NCDS and BCS70

Factor analysis was run in STATA 14.2 in NCDS and BCS70 to identify which items of the Rutter behaviour scales (Rutter, 1967) could be categorised as externalising behaviours and internalising behaviours in childhood. The results of the factor analysis are shown in Table 1.

The factor analysis yielded two factors: externalising and internalising symptoms. Factor 1 represents externalising symptoms and Factor 2 represents internalising symptoms. The table also shows the corresponding factor loadings. Overall the factor analysis gave similar results in NCDS as it did in BCS70 – although two items in BCS70 (“twitches / mannerisms” and “bites nails”) had higher factor loadings for externalising than internalising, but were classified as internalising symptoms to remain consistent with NCDS. From the factor analysis the items were categorised into externalising and internalising symptoms. The items which comprised the externalising and internalising measures in NCDS and BCS70 are listed in Table 2 and Table 3, respectively.

The internalising and externalising measures are not directly equivalent in the two cohorts as there are more items included in the measures in NCDS compared to BCS70. In NCDS, 15 items comprised the externalising measure and 10 the internalising measure, whilst in BCS70, 11 items comprised the externalising measure and 8 the internalising measure.

Table 1: Factor analysis results for internalising and externalising symptoms in NCDS and BCS70

n2316	Unresponsive / inert		
n2320	Resentful, aggressive when corrected		
n2321	Bullies other children	pa5.19	Bullies others

Table 3: Items comprising the internalising measure in NCDS and BCS70

NCDS		BCS70	
Variable name	Variable label	Variable name	Variable label
n2302	Often worries about many things	pa5.6	Often worried
n2303	Tends to be on own solitary	pa5.7	Rather solitary
n2306	Twitches	pa5.11	Twitches / mannerisms
n2307	Sucks thumb or finger	pa5.12	Sucks thumbs
n2308	Bites nails or fingers	pa5.13	Bites nails
n2312	Fearful of new situations	pa5.16	Fearful / afraid of new things
n2313	Fussy / over particular	pa5.17	Fussy / over particular
n2317	Complains of aches and pains		
n2318	Tears on arrival	pa5.9	Miserable/unhappy
n2319	Has a stutter or stammer		

Appendix 2

Derivation code

These are supplied in two parts, alongside the documentation, as part of the CLOSER Work Package 9 data download from UKDS (i.e. alongside the harmonised data files).

- The within-work package (WP) harmonisation code is provided as separate SPSS syntax files (one per study), and these are named as follows:
 - nshd_closer_wp9_harmonisation.sps
 - ncds_closer_wp9_harmonisation.sps
 - bcs_closer_wp9_harmonisation.sps
- Additional processing performed on the datasets to standardise the metadata format across the CLOSER work packages is provided as separate SPSS syntax files (one per study). These are named as follows:
 - nshd_closer_wp9_standardisation.sps
 - ncds_closer_wp9_standardisation.sps
 - bcs_closer_wp9_standardisation.sps

Source files

Files from which the derivations were made are:
